1. Achieving AC on a solved problem

1.1. **WA**.

- Check that minimal input passes.
- Can an int overflow?
- Reread the problem statement.
- Start creating small test cases with python.
- Does cout print with high enough precision?
- Abstract the implementation.

1.2. **TLE.**

- Is the solution sanity checked?
- Use pypy instead of python.
- Rewrite in C++ or Java.
- Can we apply DP anywhere?
- To minimize penalty time you should create a worst case input (if easy) to test on.
- Binary Search over the answer?

1.3. **RTE.**

- Recursion limit in python?
- Arrayindex out of bounds?
- Division by 0?
- Modifying iterator while iterating over it?
- Not using a well defined operator for Collections.sort?
- If nothing makes sense and the end of the contest is approaching you can binary search over where the error is with try-except.

1.4. MLE.

- Create objects outside recursive function.
- Rewrite recursive solution to iterative with an own stack.

2. Ideas

2.1. A TLE solution is obvious.

- If doing dp, drop parameter and recover from others.
- Use a sorted data structure.
- Is there a hint in the statement saying that something more is bounded?

2.2. Try this on clueless problems.

- Try to interpret problem as a graph (D NCPC2017).
- Can we apply maxflow, with mincost?
- How does it look for small examples, can we find a pattern?
- Binary search over solution.
- If problem is small, just brute force instead of solving it cleverly. Some times its enough to iterate over the entire domains instead of using xgcd.

3. Code Templates

```
3.1. .bashrc. Aliases.
alias p2=python2
alias p3=python3
alias nv=vim
alias o="xdg-open ."
setxkbmap -option 'nocaps:ctrl'
3.2. .vimrc. Tabs, line numbers, wrapping
set nowrap
syntax on
set tabstop=8 softtabstop=0 shiftwidth=4
set expandtab smarttab
set autoindent smartindent
set rnu number
set scrolloff=8
filetype plugin indent on
3.3. run.sh. Bash script to run all tests in a folder.
#!/bin/bash
# make executable: chmod +x run.sh
# run: ./run.sh A pypy A.py
folder=$1;shift
for f in $folder/*.in; do
    echo $f
    pre=${f%.in}
    out=$pre.out
    ans=$pre.ans
    $* < $f > $out
    diff $out $ans
```

done

```
3.4. Java Template. A Java template.
                                                                                  public String getWord() {
import java.util.*;
                                                                                      return nextToken();
import java.io.*;
public class A {
    void solve(Kattio io) {
                                                                                  private BufferedReader r;
                                                                                  private String line;
    }
                                                                                  private StringTokenizer st;
    void run() {
                                                                                  private String token;
        Kattio io = new Kattio(System.in, System.out);
        solve(io);
                                                                                  private String peekToken() {
        io.flush();
                                                                                      if (token == null)
                                                                                          try {
    public static void main(String[] args) {
                                                                                              while (st == null || !st.hasMoreTokens()) {
        (new A()).run();
                                                                                                  line = r.readLine();

def main():
    return
if __name__ == '__main__':
    main()
3.6. C++ Template. A C++ template
#include <bits/stdc++.h>
using namespace std;
#define rep(i, a, b) for(int i = a; i < (b); ++i)
#define trav(a, x) for(auto& a : x)
#define sz(x) (int)(x).size()
```

```
typedef long long ll;
typedef pair<int, int> pii;
typedef vector<int> vi;
typedef long long ll;
ll smod(ll a, ll b){
   return (a % b + b) % b;
}
int main() {
   cout.precision(9);
   cin.sync_with_stdio(0); cin.tie(0);
   cin.exceptions(cin.failbit);
   int N;
   cin >> N;
   cout << 0 << endl;
}</pre>
```

4. Data Structures

4.1. **Fenwick Tree.** Also called a Binary indexed tree. Builds in $\mathcal{O}(n \log n)$ from an array. Querry sum from 0 to i in $\mathcal{O}(\log n)$ and updates an element in $\mathcal{O}(\log n)$.

```
# Tested on: https://open.kattis.com/problems/froshweek
class FenwickTree: # zero indexed calls!
   # Give array or size!
   def __init__(self, blob):
       if type(blob) == int:
           self.sz = blob
            self.data = [0]*(blob+1)
       elif type(blob) == list:
           A = blob
           self.sz = len(A)
           self.data = [0]*(self.sz + 1)
           for i, a in enumerate(A):
                self.inc(i, a)
   \# A[i] = v
   def assign(self, i, v):
       currV = self.query(i, i)
       self.inc(i, v - currV)
   # A[i] += delta
   # this method is \sim 3x faster than doing A[i] += delta
   def inc(self, i, delta):
```

```
self.L[i], self.R[i] = lo, hi
        i += 1 \# (to 1 indexing)
        while i <= self.sz:
                                                                                       if lo == hi:
            self.data[i] += delta
                                                                                            self.value[i] = arr[lo]
            i += i&-i # lowest oneBit
                                                                                            return
    # sum(A[:i+1])
                                                                                       mid = (lo + hi)//2
    def sum(self, i):

                                                                                inc(2*i, a, b, v);
                                                                                inc(2*i+1, a, b, v);
4.3. Lazy Segment Tree. More general implementation of a segment tree where
                                                                                update(i);
its possible to increase whole segments by some diff, with lazy propagation. Imple-
mented with arrays instead of nodes, which probably has less overhead to write during
a competition.
                                                                              private void init() {
                                                                                init(1, 0, n-1, new int[n]);
class LazySegmentTree {
```

private void init(int i, int a, int b, int[] v) {

```
lo[i] = a;
    hi[i] = b;
    if(a == b) {
      sum[i] = v[a];
      return;
    int m = (a+b)/2;
    init(2*i, a, m, v);
    init(2*i+1, m+1, b, v);
    update(i);
  private void update(int i) {
    sum[i] = sum(2*i) + sum(2*i+1);
  private int range(int i) {
    return hi[i] - lo[i] + 1;
  private int sum(int i) {
    return sum[i] + range(i)*delta[i];
  private void prop(int i) {
    delta[2*i] += delta[i];
    delta[2*i+1] += delta[i];
    delta[i] = 0;
  }
}
```

4.4. **Union Find.** This data structure is used in various algorithms, for example Kruskal's algorithm for finding a Minimal Spanning Tree in a weighted graph. Also it can be used for backward simulation of dividing a set.

```
class UnionFind:
```

```
def __init__(self, N):
    self.parent = [i for i in range(N)]
    self.sz = [1]*N
def find(self, i):
    path = []
    while i != self.parent[i]:
        path.append(i)
        i = self.parent[i]
    for u in path: self.parent[u] = i
```

```
return i
def union(self, u, v):
    uR, vR = map(self.find, (u, v))
    if uR == vR: return False
    if self.sz[uR] < self.sz[vR]:
        self.parent[uR] = vR
        self.sz[vR] += self.sz[uR]
    else:
        self.parent[vR] = uR
        self.sz[uR] += self.sz[vR]
    return True</pre>
```

4.5. **Monotone Queue.** Used in sliding window algorithms where one would like to find the minimum in each interval of a given length. Amortized $\mathcal{O}(n)$ to find min in each of these intervals in an array of length n. Can easily be used to find the maximum as well.

```
private static class MinMonQue {
   LinkedList<Integer> que = new LinkedList<>();
   public void add(int i) {
      while(!que.isEmpty() && que.getFirst() > i)
            que.removeFirst();
      que.addFirst(i);
   }
   public int last() {
      return que.getLast();
   }
   public void remove(int i) {
      if(que.getLast() == i) que.removeLast();
   }
}
```

4.6. **Treap.** Treap is a binary search tree that uses randomization to balance itself. It's easy to implement, and gives you access to the internal structures of a binary tree, which can be used to find the k'th element for example. Because of the randomness, the average height is about a factor 4 of a perfectly balanced tree.

```
class Treap{
  int sz;
  int v;
  double y;
  Treap L, R;
```

```
static int sz(Treap t) {
 if(t == null) return 0;
 return t.sz;
static void update(Treap t) {
 if(t == null) return;
 t.sz = sz(t.L) + sz(t.R) + 1;
}
static Treap merge(Treap a, Treap b) {
 if (a == null) return b;
 if(b == null) return a;
 if (a.y < b.y) {
   a.R = merge(a.R, b);
   update(a);
   return a;
 } else {
    b.L = merge(a, b.L);
    update(b);
    return b;
}
//inserts middle in left half
static Treap[] split(Treap t, int x) {
 if (t == null) return new Treap[2];
 if (t.v <= x) {
   Treap[] p = split(t.R, x);
   t.R = p[0];
    p[0] = t;
   return p;
 } else {
   Treap[] p = split(t.L, x);
   t.L = p[1];
    p[1] = t;
   return p;
 }
//use only with split
static Treap insert(Treap t, int x) {
 Treap m = new Treap();
```

```
m.v = x;
 m.y = Math.random();
 m.sz = 1;
 Treap[] p = splitK(t, x-1);
  return merge(merge(p[0],m), p[1]);
//inserts middle in left half
static Treap[] splitK(Treap t, int x) {
 if (t == null) return new Treap[2];
 if (t.sz < x) return new Treap[]{t, null};</pre>
 if (sz(t.L) >= x) {
   Treap[] p = splitK(t.L, x);
   t.L = p[1];
    p[1] = t;
    update(p[0]);
    update(p[1]);
    return p;
 } else if (sz(t.L) + 1 == x){
   Treap r = t.R;
   t.R = null;
    Treap[] p = new Treap[]{t, r};
    update(p[0]);
    update(p[1]);
    return p;
 } else {
   Treap[] p = splitK(t.R, x - sz(t.L)-1);
   t.R = p[0];
    p[0] = t;
    update(p[0]);
    update(p[1]);
    return p;
//use only with splitK
static Treap insertK(Treap t, int w, int x) {
 Treap m = new Treap();
 m.v = x;
 m.y = Math.random();
```

```
m.sz = 1;
    Treap[] p = splitK(t, w);
    t = merge(p[0], m);
    return merge(t, p[1]);
  //use only with splitK
  static Treap deleteK(Treap t, int w, int x) {
    Treap[] p = splitK(t, w);
    Treap[] q = splitK(p[0], w-1);
    return merge(q[0], p[1]);
  }
  static Treap Left(Treap t) {
    if (t == null) return null;
    if (t.L == null) return t;
    return Left(t.L);
  static Treap Right(Treap t) {
    if (t == null) return null;
    if (t.R == null) return t;
    return Right(t.R);
  }
}
4.7. RMQ. \mathcal{O}(1) queries of interval min, max, gcd or lcm. \mathcal{O}(n \log n) building time.
import math
class RMQ:
    def __init__(self, arr, func=min):
        self.sz = len(arr)
        self.func = func
        MAXN = self.sz
        LOGMAXN = int(math.ceil(math.log(MAXN + 1, 2)))
        self.data = [[0]*LOGMAXN for _ in range(MAXN)]
        for i in range(MAXN):
            self.data[i][0] = arr[i]
        for j in range(1, LOGMAXN):
            for i in range(MAXN - (1 << j)+1):
                 self.data[i][j] = func(self.data[i][j-1],
                         self.data[i + (1<<(j-1))][j-1])
```

```
def query(self, a, b):
    if a > b:
        # some default value when query is empty
        return 1
    d = b - a + 1
    k = int(math.log(d, 2))
    return self.func(self.data[a][k], self.data[b-(1<<k)+1][k])</pre>
```

5. Graph Algorithms

5.1. **Dijkstras algorithm.** Finds the shortest distance between two Nodes in a weighted graph in $\mathcal{O}(|E| \log |V|)$ time.

```
from heapq import heappop as pop, heappush as push
# adj: adj-list where edges are tuples (node_id, weight):
# (1) --2-- (0) --3-- (2) has the adj-list:
\# adj = [[(1, 2), (2, 3)], [(0, 2)], [0, 3]]
def dijk(adj, S, T):
    N = len(adj)
    INF = 10**18
    dist = [INF]*N
    [] = pq
    def add(i, dst):
        if dst < dist[i]:</pre>
            dist[i] = dst
            push(pq, (dst, i))
    add(S, 0)
    while pq:
        D, i = pop(pq)
        if i == T: return D
        if D != dist[i]: continue
        for j, w in adj[i]:
            add(j, D + w)
    return dist[T]
```

5.2. **Bipartite Graphs.** The Hopcroft-Karp algorithm finds the maximal matching in a bipartite graph. Also, this matching can together with Köning's theorem be used to construct a minimal vertex-cover, which as we all know is the complement of a maximum independent set. Runs in $\mathcal{O}(|E|\sqrt{|V|})$.

```
import java.util.*;
                                                                                      Q.addLast(U[Pair[v.id]]);
class Node {
                                                                                    }
  int id;
                                                                                  }

5.3. **Network Flow.** Ford-Fulkerson algorithm for determining the maximum flow through a graph can be used for a lot of unexpected problems. Given a problem that can be formulated as a graph, where no ideas are found trying, it might help trying to apply network flow. The running time is $\mathcal{O}(C \cdot m)$ where C is the maximum flow and m is the amount of edges in the graph. If C is very large we can change the running time to $\mathcal{O}(\log Cm^2)$ by only studying edges with a large enough capacity in the beginning.

```
# used in mincut @ Kattis
from collections import defaultdict

6. Dynamic Programming

6.1. Longest Increasing Subsequence. Finds the longest increasing subsequence in an array in $\mathcal{O}(n \log n)$ time. Can easily be transformed to longest decreasing/non decreasing/non increasing subsequence.

```
def lis(X):
    N = len(X)
    P = [0]*N
    M = [0]*(N+1)
    L = 0
    for i in range(N):
        lo, hi = 1, L + 1
        while lo < hi:</pre>
```

```
mid = (lo + hi) >> 1
    if X[M[mid]] < X[i]:
        lo = mid + 1
    else:
        hi = mid
    newL = lo
    P[i] = M[newL - 1]
    M[newL] = i
    L = max(L, newL)

S = [0]*L
k = M[L]
for i in range(L-1, -1, -1):
    S[i] = X[k]
k = P[k]
return S</pre>
```

6.2. **String functions.** The z-function computes the longest common prefix of t and t[i:] for each i in $\mathcal{O}(|t|)$. The border function computes the longest common proper (smaller than whole string) prefix and suffix of string t[:i].

```
def zfun(t):
   z = [0]*len(t)
   n = len(t)
   l, r = (0,0)
    for i in range(1,n):
        if i < r:
            z[i] = min(z[i-l], r-i+1)
        while z[i] + i < n and t[i+z[i]] == t[z[i]]:
            z[i] +=1
        if i + z[i] - 1 > r:
           l = i
            r = i + z[i] - 1
    return z
def matches(t, p):
    s = p + '#' + t
    return filter(lambda x: x[1] == len(p),
            enumerate(zfun(s)))
def boarders(s):
    b = [0]*len(s)
```

```
for i in range(1, len(s)):
    k = b[i-1]
    while k>0 and s[k] != s[i]:
        k = b[k-1]
    if s[k] == s[i]:
        b[i] = k+1
return b
```

element is continuously removed?

```
# Rewritten from J(n, k) = (J(n-1, k) + k)%n
def J(n, k):
   r = 0
   for i in range(2, n+1):
        r = (r + k)\%i
   return r
```

6.4. Floyd Warshall. Constructs a matrix with the distance between all pairs of nodes in $\mathcal{O}(n^3)$ time. Works for negative edge weights, but not if there exists negative cycles. The nxt matrix is used to reconstruct a path. Can be skipped if we don't care about the path.

```
# Computes distance matrix and next matrix given an edgelist
def FloydWarshall(n, edges):
   INF = 10**9
   dist = [[INF]*n for _ in range(n)]
   nxt = [[None]*n for _ in range(n)]
   for e in edges:
        dist[e[0]][e[1]] = e[2]
        nxt[e[0]][e[1]] = e[1]
   for k in range(n):
        for i in range(n):
            for j in range(n):
                if dist[i][j] > dist[i][k] + dist[k][j]:
                    dist[i][j] = dist[i][k] + dist[k][j]
                    nxt[i][j] = nxt[i][k]
    return dist, nxt
# Computes the path from i to j given a nextmatrix
def path(i, j, nxt):
   if nxt[i][j] == None: return []
```

```
path = [i]
while i != j:
   i = nxt[i][j]
    path.append(i)
return path
```

7. ETC

6.3. Josephus problem. Who is the last one to get removed from a circle if the k'th 7.1. System of Equations. Solves the system of equations Ax = b by Gaussian elimination. This can for example be used to determine the expected value of each node in a markov chain. Runns in $\mathcal{O}(N^3)$.

```
# monoid needs to implement
# __add__, __mul__, __sub__, __div__ and isZ
def gauss(A, b, monoid=None):
   def Z(v): return abs(v) < 1e-6 if not monoid else v.isZ()
   N = len(A[0])
   for i in range(N):
       trv:
           m = next(j for j in range(i, N) if Z(A[j][i]) == False)
        except:
            return None #A is not independent!
       if i != m:
           A[i], A[m] = A[m], A[i]
            b[i], b[m] = b[m], b[i]
       for j in range(i+1, N):
            sub = A[i][i]/A[i][i]
           b[j] -= sub*b[i]
           for k in range(N):
                A[i][k] = sub*A[i][k]
   for i in range(N-1, -1, -1):
        for j in range(N-1, i, -1):
            sub = A[i][j]/A[j][j]
            b[i] -= sub*b[i]
        b[i], A[i][i] = b[i]/A[i][i], A[i][i]/A[i][i]
   return b
```

7.2. Convex Hull. From a collection of points in the plane the convex hull is often used to compute the largest distance or the area covered, or the length of a rope that

```
encloses the points. It can be found in \mathcal{O}(N \log N) time by sorting the points on angle # where g = x0*a + y0*b
and the sweeping over all of them.
                                                                             def xqcd(a, b):
                                                                                x0, x1, y0, y1 = 1, 0, 0, 1

7.4. **FFT.** FFT can be used to calculate the product of two polynomials of length N in $\mathcal{O}(N \log N)$ time. The FFT function requires a power of 2 sized array of size at least 2N to store the results as complex numbers.

```
import cmath
# A has to be of length a power of 2.
def FFT(A. inverse=False):
    N = len(A)
    if N <= 1:
        return A
    if inverse:
        D = FFT(A) \# d_0/N, d_{N-1}/N, d_{N-2}/N, ...
        return map(lambda x: x/N, [D[0]] + D[:0:-1])
    evn = FFT(A[0::2])
    odd = FFT(A[1::2])
    Nh = N//2
    return [evn[k%Nh]+cmath.exp(2j*cmath.pi*k/N)*odd[k%Nh]
            for k in range(N)]
# A has to be of length a power of 2.
def FFT2(a, inverse=False):
    N = len(a)
    i = 0
    for i in range(1, N):
        bit = N >> 1
        while j&bit:
            i ^= bit
            bit >>= 1
        j^= bit
        if i < j:
            a[i], a[j] = a[j], a[i]
    I = 2
    MUL = -1 if inverse else 1
    while L <= N:
        ang = 2j*cmath.pi/L * MUL
        wlen = cmath.exp(ang)
        for i in range(0, N, L):
            w = 1
```

for j in range(L//2):

```
u = a[i+j]
                v = a[i+j+L//2] * w
                a[i+j] = u + v
                a[i+j+L//2] = u - v
                w *= wlen
        L *= 2
   if inverse:
        for i in range(N):
            a[i] /= N
    return a
def uP(n):
    while n != (n\&-n):
        n += n&-n
    return n
\# C[x] = sum_{i=0..N}(A[x-i]*B[i])
def polymul(A, B):
    sz = 2*max(uP(len(A)), uP(len(B)))
   A = A + [0]*(sz - len(A))
   B = B + [0]*(sz - len(B))
    fA = FFT(A)
    fB = FFT(B)
    fAB = [a*b for a, b in zip(fA, fB)]
    C = [x.real for x in FFT(fAB, True)]
    return C
```

8. NP Tricks

8.1. MaxClique. The max clique problem is one of Karp's 21 NP-complete problems. The problem is to find the largest subset of an undirected graph that forms a clique - a complete graph. There is an obvious algorithm that just inspects every subset of the graph and determines if this subset is a clique. This algorithm runs in $\mathcal{O}(n^2 2^n)$. However one can use the meet in the middle trick (one step divide and conquer) and reduce the complexity to $\mathcal{O}(n^2 2^{\frac{n}{2}})$.

```
static int max_clique(int n, int[][] adj) {
  int fst = n/2;
```

```
int snd = n - fst;
int[] maxc = new int[1<<fst];</pre>
int max = 1;
for(int i = 0; i < (1 << fst); i++) {
 for(int a = 0; a<fst; a++) {</pre>
    if((i&1<<a) != 0)
      maxc[i] = Math.max(maxc[i], maxc[i^(1<<a)]);
 boolean ok = true;
 for(int a = 0; a<fst; a++) if((i\&1<<a) != 0) {
    for(int b = a+1; b<fst; b++) {</pre>
        if((i\&1 << b) != 0 && adj[a][b] == 0)
            ok = false:
    }
 }
 if(ok) {
    maxc[i] = Integer.bitCount(i);
    max = Math.max(max, maxc[i]);
for(int i = 0; i < (1 << snd); i++) {
 boolean ok = true;
 for(int a = 0; a < snd; a++) if((i \& 1 << a) != 0) {
    for(int b = a+1; b<snd; b++) {
      if((i\&1 << b) != 0)
        if(adj[a+fst][b+fst] == 0)
          ok = false;
    }
 if(!ok) continue;
 int mask = 0;
 for(int a = 0; a<fst; a++) {
    ok = true;
    for(int b = 0; b < snd; b++) {
      if((i&1<<b) != 0) {
        if(adi[a][b+fst] == 0) ok = false:
    if(ok) mask = (1 << a);
```

9. Coordinate Geometry

9.1. **Area of a nonintersecting polygon.** The signed area of a polygon with n vertices is given by

$$A = \frac{1}{2} \sum_{i=0}^{n-1} (x_i y_{i+1} - x_{i+1} y_i)$$

9.2. **Intersection of two lines.** Two lines defined by

$$a_1x + b_1y + c_1 = 0$$
$$a_2x + b_2y + c_2 = 0$$

Intersects in the point

$$P = (\frac{b_1c_2 - b_2c_1}{w}, \frac{a_2c_1 - a_1c_2}{w}),$$

where $w = a_1b_2 - a_2b_1$. If w = 0 the lines are parallel.

9.3. Distance between line segment and point. Given a line segment between point P, Q, the distance D to point R is given by:

$$\begin{split} a &= Q_y - P_y \\ b &= Q_x - P_x \\ c &= P_x Q_y - P_y Q_x \\ R_P &= (\frac{b(bR_x - aR_y) - ac}{a^2 + b^2}, \frac{a(aR_y - bR_x) - bc}{a^2 + b^2}) \\ D &= \begin{cases} \frac{|aR_x + bR_y + c|}{\sqrt{a^2 + b^2}} & \text{if } (R_{P_x} - P_x)(R_{P_x} - Q_x) < 0, \\ \min |P - R|, |Q - R| & \text{otherwise} \end{cases} \end{split}$$

9.4. **Picks theorem.** Find the amount of internal integer coordinates i inside a polygon with picks theorem $A = \frac{b}{2} + i - 1$, where A is the area of the polygon and b is the amount of coordinates on the boundary.

9.5. **Trigonometry.** Sine-rule

$$\frac{\sin(\alpha)}{a} = \frac{\sin(\beta)}{b} = \frac{\sin(\gamma)}{c}$$

Cosine-rule

$$a^2 = b^2 + c^2 - 2bc \cdot \cos(\alpha)$$

Area-rule

$$A = \frac{a \cdot b \cdot \sin(\gamma)}{2}$$

Rotation Matrix, rotate a 2D-vector θ radians by multiplying with the following matrix.

$$\begin{bmatrix} \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta \end{bmatrix}$$

9.6. Implementations.

10. Practice Contest Checklist

- Operations per second in py2
- Operations per second in py3
- Operations per second in java
- Operations per second in c++
- Operations per second on local machine
- Is MLE called MLE or RTE?
- What happens if extra output is added? What about one extra new line or space?
- Look at documentation on judge.
- Submit a clarification.
- Print a file.
- Directory with test cases.
